THIS PAGE BLANK (USPTO)

Handling of circuit-switched data services in IP-based GSM networks

5 The present invention relates to a communication network part, and a method for operating in a communication network part.

10 Recently, there have been made attempts in a more and more increasing manner to couple and to integrate a mobile cellular telephone network, for instance, the GSM network that is generally a circuit switched network to a further kind of networks, called packet switched networks, for instance, an internet protocol network or VoIP (Voice over Internet Protocol) network, wherein call information is transferred in the form of "packets" between the called member and the calling member and vice versa. The packet switched network uses several different ways or through-connections to transfer the packets between the users, whereas in the circuit switched world, for instance, the GSM network, a through-connection is established within the network and, as long as the through-connection is maintained, the whole call information including signalling and payload information is transferred via the through-connection in the circuit switched network between the users.

25 A through-connection in a communication network that comprises, for instance, a GSM (Global System for Mobile communication) network or a similar cellular telephone network and packet switched network being coupled with each other by interface means is established in the conventional cellular telephone network via a base transceiver station, a base station controller and a mobile services switching

centre to the interface that in turn is coupled to the internet protocol network or packet switched network.

Each node in a packet switched network which processes the
5 payload information causes some delay in the payload transfer. Further the transport of payload information over a combined circuit switched network with packet switched network requires high bandwidth for every allocated
10 channel. It means in some cases 64kbps for every channel has to be allocated, which causes a high waste of transmission resources. This means the known architecture of the GSM telephone network is improper or not very well suited for coupling to a packet switched network.

15 Thus it is an object of the present invention to provide a communication network part that has a new cellular telephone network architecture and a method for information flow in this communication network part which minimise the delay problems and bandwidth requirements.

20 This object is solved by the communication network part of claim 1 and by the method in accordance to claim 19.

Accordingly, it is an advantage of the present invention
25 that it is possible to support GSM circuit switched data services within IP based GSM networks with a higher transmission efficiency than in the case of the state of the art GSM systems. Inter alia, this advantage is obtained by the discontinuous transmission (DTX) layer used in the
30 protocol stack of the invention. The DTX layer or function integrated in BTS makes sure that no empty frames are being sent over the link to a media gateway when the mobile station is not sending any user data. Similar the in media

gateway integrated DTX layer or function makes sure that no data is being sent to mobile station when no data is received from a further network. By discarding these empty frames, the data rate can be improved. The data rate can be further decreased by implementation the rate adaptation function in a radio network mean for example base transceivers station (BTS).

Further advantageous improvements of the present invention are mentioned in the claims 2 to 18 and 20 to 23. Further objects, advantages, advantageous improvements and applications of the invention are mentioned in the following description of a preferred embodiment of the invention in connection with the enclosed figures.

Fig. 1: a schematic block diagram of a preferred embodiment of the packet switched protocol based cellular telephone network of the present invention, e.g. a GSM network being coupled to a further network, for instance, a GSTN network,

Fig. 2: a schematic block diagram of a first user plane protocol stack for asynchronous non-transparent bearer services in the cellular telephone network of Fig. 1,

Fig. 3: a schematic block diagram of a second user plane protocol stack for synchronous non-transparent bearer services in the cellular telephone network of Fig. 1,

Fig. 4: a schematic block diagram of a third user plane protocol stack for asynchronous transparent bearer services in the cellular telephone network of Fig. 1,

Fig. 5: a schematic block diagram of a fourth user plane protocol stack for synchronous transparent bearer services in the cellular telephone network of Fig. 1,

5 Fig. 6: a schematic block diagram of a fifth user plane protocol stack for asynchronous non-transparent high-speed circuit-switched data bearer services in the cellular telephone network of figure 1.

10 The present invention relates to a communication network part, and a method for operating in a communication network part. The communication network part comprises a first layer for transferring signalling information assigned to a telephone call being processed in the cellular telephone
15 network and a second layer for transferring payload information assigned to the telephone call. Further an interface mean couples the cellular telephone network to a further network. The interface means comprise a signalling information exchange function and user or so-called payload
20 information exchange function between the cellular telephone network and the further network. The first layer and the second layer of the cellular telephone network being coupled to the interface means. The second layer comprises information frame generating means for generating
25 an information frame comprising user information of the telephone call and being transferred to and from the interface means on a direct route assigned to the telephone call within the second layer and a frame suppressing function for suppressing the transfer of an information
30 frame within the second layer if the information frame does not comprise any user information. The second layer comprises also radio network means comprising a rate adaptation function for a rate adaptation of the payload

information transfer assigned to the telephone call. With this step the rate adaptation function is shifted from an interworking function into a radio network means, for example base transceiver station (BTS).

5

In figure 1 a schematic block diagram of a preferred embodiment of the packet switched protocol based cellular telephone network of the invention is shown. The cellular telephone network 1 comprises an interface 20 for coupling
10 to a further network 2. In the following the invention is described by example using a GSM network as cellular telephone network 1 and a GSTN network as further network.

The cellular telephone network 1 of the invention is
15 divided into a first layer 3 or level, also called an application or signalling information processing and transferring platform, comprising application and network service functions and into a second layer 4 or level, also called a transmission or payload information transferring
20 platform, that performs call information transmission or payload or user information transmission and communication, for instance, in an internet protocol (IP) format. Further the interface means 20 are provided in order to couple the cellular telephone network 1 to the switched packet network
25 for bi-directional information exchange between these networks or network parts.

The second layer 4 of the GSM network comprises several base transceiver stations BTS 7, 8 and 9 as part of a base
30 station subsystem. Each base transceiver station 7, 8, 9 houses the radio transceivers that define a cell being assigned to a cell area and handles the radio link 6 that

is the connection to a number of fixed or mobile stations 5 existing in the corresponding cell area.

As shown in figure 1 on the second layer 4, the base
5 transceiver station 8 is connected by means of a direct connection 11 or route, also called a through-connection, to a media gateway 10 of the interface means 20. The base transceiver station, therefore, comprises the functionality and protocol for sending and receiving call and payload or
10 user information from or to the media gateway 10 via the direct protocol connection 11. The base transceiver station handles user data information to be sent and received over the direct protocol connection between the base transceiver station and the media gateway of the interface. Further, in
15 order to serve the device control protocol connection 13 between the base transceiver station 8 and the base station controller 14, control protocol software is implemented on both the base transceiver station 8 and the base station controller 14 on the basis of GCP (Gateway Control
20 Protocol) protocols, for example from ITU-T the H.248 protocol or the MGCP protocol from IETF.

The media gateway 10 substantially provides a payload conversion between the packet switched GSM network 1 and
25 the packet switched network, for example an internet protocol network, or a circuit switched network, or the GSTN as further network 2. The media gateway 10 of the interface means 20 comprises devices such as transcoders, modems, ISDN terminals, a network access server etc.
30 Further the media gateway 10 comprises the functionality and control software being required for transferring payload, user or call information directly to the base transceiver stations 7, 8, 9. The media gateway 10 handles

user data information to be sent and received over the direct protocol connection between the media gateway 10 and a base transceiver station. On the direct connection 11 from the base transceiver station 8 to the media gateway 10 user information is transferred with a transmission rate, for instance, of 9.6 kbps. On a payload connection 25 from the media gateway 10 to the further network 2 or the internet protocol network the transmission rate corresponds to, for instance, 64 kbps.

10

The first layer 3 of the GSM cellular telephone network used in the invention comprises a number of base station controllers, wherein in the figure 1 one base station controller 14 is shown, a number of mobile services switching centres, wherein one mobile switching center 16 is shown in figure 1, a home location register (HLR) 18 and a number of visitor location registers (VLR), wherein only one VLR 23 is shown in the figure 1. The home location register 18 contains all the administrative information of each subscriber registered in the GSM network along with the current VLR-location of the mobile stations 5. The visitor location register 23 contains selected administrative information from the home location register 18 necessary for call control and provision of the subscribed services for each fixed station or mobile station 5 currently located in the geographical area controlled by the visitor location register 23. The home location register 18 and the visitor location register 23 together with the mobile services switching center 16 provide the call routing and possibly international roaming capabilities of the GSM network. Further units, for instance, the equipment identity register that contains a

list of valid mobile equipment on the GSM network and an authentication centre are not shown in the figures.

The base station controller 14 and the mobile services
5 switching centre 16 are connected via an application
signalling protocol connection 15 and the mobile services
switching centres 16 is also connected to the home location
register 18 via an application signalling protocol
connection. The application signalling protocol connection
10 15 is, for instance, implemented on the basis of the known
MAP (Mobile Application Part) or BSSMAP (Base Station
System Management Application Part) protocols.

The mobile services switching centre 16 is the main
15 component of the layer 3 and provides all the functionality
needed to handle a mobile subscriber or a mobile station 5,
such as registration, authentication, location updating and
call routing to a roaming subscriber. Further, in the
mobile services switching center 16 a MSC device control
20 protocol is implemented for controlling the media gateway
10 of the interface means 20 via a MSC device control
protocol connection 17 between the media gateway 10 and the
mobile services switching center 16. For instance, this MSC
device control protocol can be implemented in the mobile
25 services switching center 16 on the basis of a gateway
control protocol, like for example the ITU-T H.248 or the
MGCP (Media Gateway Control Protocol) from ITU or the ITU
MEGACOP (MEdia Gateway Control Protocol).

30 Further on the layer 3 of the GSM network a signalling
gateway 21, for instance, a SS7 (Signalling System Number
7) gateway, as part of the interface means 20 is shown
which, for instance, provides signalling bearer conversions

between circuit or packet switched protocols and packet switched protocols or vice versa. It may also provide application level signalling conversions between different protocols. The signalling gateway 21 is connected to the
5 further network via an interface protocol connection 26. Further the signalling gateway 21 of the interface means 20 is connected to the mobile services switching center 16 by means of a trunk signalling protocol 22.

10 Figure 2 shows a schematic block diagram of a first user plane protocol stack for asynchronous non-transparent bearer services in the cellular telephone network of figure 1.

15 The non-transparent bearer service means that at a layer_2 of a protocol stack, the so-called link layer, the RLP (Radio Link Protocol) is available, which guarantees a reliable data transmission. In case of transparent bearer service an unreliable data transmission is given at a
20 layer_2, it means the RLP is not available on a link layer. A more detailed description for transparent and non-transparent bearer services is given below.

In case of an asynchronous bearer services the transmission
25 of bits is not aligned on a regular time clock, whereas it is in the synchronous case. A protocol for asynchronous transmission groups the bits in units for example of 7 to 9 bits, so-called characters, whereby a character is preceded and followed by special signals, the so-called start and
30 the stop bits. In the synchronous case, bits are transmitted regularly and continuously on the base of a time clock.

In more detail, figure 2 shows, in connection with figure 1, a first protocol stack 31 being implemented in the mobile station TE/MS, a second protocol stack 32 being implemented in the base transceiver station BTS and a third
5 protocol stack 33 being implemented in the media gateway Media Gateway.

The first to third protocol stacks 31, 32 and 33 are established to provide the transmission of user data.
10 According to figure 1 the transmission of user data is performed within the transmission layer 4 or user plane, for example from the mobile station 5 or user or end terminal via the radio link 6, the base transceiver station 8 and the direct connection 11 to the media gateway 10 and
15 vice versa, it means from the media gateway 10 via the direct connection 11, the base transceiver station 8 and the radio link 6 to the mobile station 5 or user end terminal. A data transmission from the mobile station 5 to the media gateway 10 is so-called an uplink transmission
20 whereas a data transmission that is performed in the opposite direction, it means from the media gateway 10 to the mobile station 5, is so-called a downlink transmission.

The first protocol stack 31 of figure 2 implemented in the
25 mobile station TE/MS comprises a sequence of protocol functions, which an user data stream has to pass from or to an application layer that is a source of user data in uplink transmission and a drain of user data or user information in downlink transmission. The protocol function
30 sequence of the uplink transmission in the first stack 31 comprises an application layer Appl, an RA0 function, an RA1 function, an L2R function, an RLP function an RA1' function and a forward error correction FEC function in

this order wherein the data stream output from the FEC function is transferred via the radio link to the base transceiver station BTS. In this regard, it should be remarked that the expressions "layer", "protocol" each
5 represent an equivalent meaning for "function" used here and in the following description.

In the following, the case of uplink data transmission within the mobile station TE/MS is described in more
10 detail.

The RA0 function converts an incoming asynchronous user data stream that is output from the application layer to a synchronous data stream. For instance, the RA0 function
15 converts the incoming asynchronous data stream having an user data rate of 9.6 kbps into a synchronous data stream having an user data rate of 9.6 kbps. A more detailed description of the RA0 function is disclosed in GSM 04.21 "Digital cellular telecommunications system (Phase 2+);
20 Rate adaption on the Mobile Station- Base Station System (MS - BSS) Interface (GSM 04.21 version 5.2.1)" published by the European Telecommunications Standards Institute (ETSI) in 1998 (in the following referred to as "GSM 04.21"). The synchronous data stream resulting from the RA0
25 function is fed to the RA1 function.

The RA1 function converts the incoming synchronous user data stream to a synchronous data stream having a data rate being higher than the incoming data rate. For instance, the
30 RA1 function converts the incoming synchronous data stream having the user data rate of 9.6 kbps into a synchronous data stream having an intermediate user data rate of 16 kbps. A detailed description of the RA1 function is

disclosed again in the GSM 04.21 paper, pp. 11 to 14. The synchronous data stream resulting from the RA1 function is fed to the L2R-function.

- 5 The Layer_2 Relay (L2R) function converts the incoming synchronous user data stream that is output from the RA1 function to a data stream that can be processed by the Radio Link Protocol RLP function. In general the L2R fulfils some tasks of the link layer protocol. In
- 10 particular the L2R is responsible for flow control and buffering of packets. The first mechanism is used to control the transmission rate at which a node injects packets into a network to avoid congestion either on the transmission link or at the receiver. The second method
- 15 allows a buffering of the copies of the sent packets in order of a possible retransmission in case during a transmission an error occurs. A more detailed description of the L2R function is disclosed in "Digital cellular telecommunications system (Phase 2+); Radio Link Protocol
- 20 (RLP) for data and telematic services on the Mobile Station - Base Station System (MS - BSS) interface and the Base Station system - Mobile-services Switching Centre (BSS - MSC) interface (GSM 04.22 version 7.0.0 release 1998)" Mobile Station- Base Station System (MS - BSS) Interface
- 25 (GSM 04.22 version 5.2.1)" published by the European Telecommunications Standards Institute (ETSI) (in the following referred to as "GSM 04.22"). The data stream resulting from the L2R function is fed to the RLP function.
- 30 The task of the RLP layer is detection and correction of the failed transmitted packets to ensure reliability of the transmission. This task is realised by applying a single fundamental technique known as positive acknowledgement

with retransmission. The technique requires a recipient sending back an acknowledgement to the sender as it receives data. The sender keeps a copy of each packet it sends as this is done on the L2R layer, and waits for an
5 acknowledgement before sending the following packet or data stream. The RLP on the sender side also starts a timer when it sends a packet. In case the timer expires before an acknowledgement arrives or in case that sender receives an acknowledgement message requiring sending anew a packet
10 this causes the assumption on the sender side the packet was lost and a retransmission is started. A retransmission of a packet performs the correction of the error.

The RLP function processes the incoming data stream into
15 RLP frames that are sent in strict alignment with the radio transmission data. Generally, an RLP frame is a sequence of contiguous bits representing an RLP procedural element. The generated RLP frames are of a fixed size of, for instance, 240 bits or 576 bits. Whenever an RLP frame is to be sent
20 the RLP function or RLP entity has to provide the necessary protocol information to be contained in it. There are different types of RLP frames, for example a so-called I + S frame that is used for user information transfer and that carries supervisory information in a piggybacked manner, an
25 S frame that contains supervisory information in the absence of user data information and a U frame that contains unnumbered protocol information. The basic frame structure of an RLP frame comprises a header, for example 16 or 24 bit transferring control information, an
30 information field, for example 200, 192, 536 or 528 bit and a frame check sequence (FSC), for example 24 bit that is a field of redundant information based on a cyclic code and being used for error detection, in this order.

The header or header format of the S frame, inter alia, contains information for specifying the S frame. For instance, a "011111" word carried in the bits with the bit number 4 to 9 of the header specifies the frame to be an S frame. Further, the header of the S frame comprises a receive sequence number N(R) field. The number N(R) designates the next information frame to be sent by the other RLP entity. The N(R) number is, for instance, 6 bit (version 0 and 1 frames) or 9 bit (version 2 frames) long and it occupies the 11th to 16th bit (version 0 and 1 frames) or the 14th to 22nd bit (version 2 frames) of the header. The bit 24 position of the header (only version 2 headers) can be occupied by an upgrading proposal bit (UP bit) that may be used by the inter working function that, for instance, can be established in the interface means 20, particularly in the media gateway 10 for constituting the interface to the further network 2 shown in figur 1, to indicate to the mobile station 5 that a service level upgrading will increase the throughput. A more detailed description of the RLP entity and of the RLP frames is made in the GSM 04.22 document and the specifications mentioned therein.

Subsequent to the RLP entity or protocol layer the stack 31 of the mobile station TE/MS has RA1' converter or function. The RA1' function converts the incoming user data stream that is output from the RLP function to a synchronous data stream having a data rate being lower than the incoming data rate. For instance, the RA1' function converts the incoming synchronous data stream having the RLP data rate or intermediate data rate of 16 kbps into a synchronous data stream having a radio interface rate or user data rate

of 12 kbps. A detailed description of the RA1' function is disclosed again in the GSM 04.21 paper. The synchronous data stream resulting from the RA1' function is fed to the FEC function.

5

The FEC function provides a forward error correction of the data stream received from the RA1' converter and adds corresponding redundant information for error correction to the RA1' data stream. Therefore, the FEC function increases the incoming RA1' data rate, for instance, from 12 kbps to 22.8 kbps. The data stream output from the FEC function is forwarded via the radio link to the second protocol stack 32. A detailed description can be found in ETSI 05.08 and ETSI 05.38.

10

15

In the following, the case of downlink data transmission within the user end terminal or the mobile station TE/MS is described in more detail. In the direction of the downlink transmission, the sequence of the first protocol stack 31 in the mobile station TE/MS comprises the FEC function, the RA1' function, the RLP function, the L2R function, the RA1 function and the RA0 function in this order wherein the data stream output from the RA0 function is input to application layer.

20

25

First, the FEC function of the first stack 31 terminates the forward error correction of the synchronous data stream received via the radio link from the second stack 32 of the base transceiver station BTS. It processes and reduces or eliminates the redundant information for error correction in order to output a synchronous data stream prepared for processing in the RA1' function. Therefore, the FEC function decreased the incoming data rate, for instance,

30

from 22.8 kbps to 12 kbps. The data stream output from the FEC function is input to the RA1' function of the first stack 31.

5 Subsequently, the RA1' function of the protocol stack 31 of the mobile station TE/MS converts the incoming synchronous data stream that is output from the FEC function to a synchronous data stream having a data rate being higher than the incoming data rate. For instance, the RA1'
10 function converts the incoming synchronous data stream having the radio interface data rate of 12 kbps into a synchronous data stream having a intermediate data rate of 16 kbps. Again, a detailed description of the RA1' function is disclosed again in the GSM 04.21 paper. The synchronous
15 data stream resulting from the RA1' function is fed to the RLP function or RLP entity in the mobile station TE/MS.

The RLP function processes the incoming data stream that is in the above described format of RLP frames and prepares a
20 data stream to be processed in the subsequent L2R layer.

The Layer_2 Relay (L2R) function converts the incoming synchronous user data stream that is output from the RLP function to a synchronous data stream that can be processed
25 in the subsequent RA1 function, i.e. also the L2R layer is terminated in the first stack 31 of the mobile station TE/MS in downlink transmission of data.

The subsequent RA1 function converts the incoming
30 synchronous user data stream that is output from the L2R function to a synchronous data stream having a data rate being lower than the incoming data rate. For instance, the RA1 function converts the incoming synchronous data stream

having the intermediate data rate of 16 kbps into a synchronous data stream having the user data rate of 9.6 kbps. The synchronous data stream resulting from the RA1 function is fed to the RA0 function.

5

The RA0 function converts the incoming synchronous user data stream that is output from the RA1 function to the asynchronous data stream. For instance, the RA0 function converts the incoming synchronous data stream having the user data rate of 9.6 kbps into the asynchronous data stream having the user data rate of 9.6 kbps. The asynchronous data stream resulting from the RA0 function is fed to the application layer Appl being a drain for the asynchronous user data.

10

15

The second protocol stack 32 shown in figure 2 which is implemented in the base station transceiver BTS comprises a sequence of protocol functions, a user data stream has to pass through.

20

The protocol function sequence in the direction of uplink transmission in the protocol stack 32 comprises the above described FEC function, the RA1' function, the RA1 function, the RA0 function, a Relay function, a discontinuous transmission DTX function, a user datagram protocol UDP function, an internet protocol IP function, a Layer_2 L2 function and a Layer_1 L1 function in this order wherein the data stream output from the L1 function is transferred via the direct connection 11 to the media gateway 10, according to figure 1.

25

30

In the following, the case of uplink data transmission within the second stack 32 of the base transceiver station BTS is described in more detail.

5 First, the FEC function of the second stack 32 terminates the forward error correction of the synchronous data stream received via the radio link from the first stack 31 of the mobile station TE/MS. It processes and reduces or
10 eliminates the redundant information for error correction in order to output a synchronous data stream prepared for processing in the RA1' function. Therefore, the FEC function decreases the incoming data rate, for instance, from 22.8 kbps to 12 kbps. The data stream output from the
15 FEC function is input to the RA1' function of the second stack 32.

Subsequently, the RA1' function of the second stack 32 of the base transceiver station BTS converts the incoming synchronous data stream that is output from the FEC
20 function to a synchronous data stream having a data rate being higher than the incoming data rate. For instance, the RA1' function converts the incoming synchronous data stream having the radio interface data rate of 12 kbps into a synchronous data stream having the intermediate data rate
25 of 16 kbps. For detailed description of the RA1' function please refer to the GSM 04.21 paper. The synchronous data stream resulting from the RA1' function is fed to the RA1 function in the base transceiver station BTS.

30 The subsequent RA1 function converts the incoming synchronous user data stream that is output from the RA1' function to the synchronous data stream having a data rate being lower than the incoming data rate. For instance, the

RA1 function converts the incoming synchronous data stream having the intermediate data rate of 16 kbps into a synchronous data stream having the user data rate of 9.6 kbps. The synchronous data stream resulting from the RA1 function is fed to the RA0 function, which converts the incoming synchronous user data stream that is output from the RA1 function to the asynchronous data stream. The asynchronous data stream is relayed to the DTX function.

10

The DTX function performs a frame suppression or discarding function for suppressing the transfer of an information frame generated in the RLP layer or entity in the first stack 31 or in the third stack 33 of the media gateway within the second layer 4, according to figure 1, if the RLP information frame does not comprise any user information. The DTX function detects the frame not comprising any user information on the basis of information specifying that the information frame does not provide any user information. The DTX function, for instance, detects the "011111" word in the header of the current information frame which, therefore, is an S frame that does not contain any user or payload information. In the case the DTX function detects an S frame the DTX function then verifies the receive sequence number N(R) field of the header of the detected S frame. If the DTX function in the base station transceiver BTS receives an S frame and the N(R) of the current S frame is equal to the previous frame or S frame then the DTX function discards or suppresses this current S frame from further transmission in order to decrease the data rate. The data stream output from the DTX layer is input to the following UDP function.

The UDP function provides a procedure for converting the synchronous data stream output from the DTX function into a data stream prepared for the subsequent IP function within the second stack 32 of the base transceiver station BTS.

5 The UDP header format comprises, inter alia, a source port field and a destination port field. The destination port field is loaded with address information assigned to the media gateway and the source port field is loaded with address information assigned to the base transceiver
10 station BTS. A more detailed description of the UDP function used in this network is published in "User Datagram Protocol" by J. Postel in RFC 768 (<http://www.ietf.cnri.reston.va.us/rfc/rfc0768.txt>), 1980, and in the documents mentioned therein.

15

The data stream output from the UDP function is input to the IP function in the second stack 32 of the base transceiver station BTS. The IP function, inter alia, is designed for use in interconnection of the base transceiver
20 station BTS and the media gateway for packet switched communication and data transmission between them. The IP function provides for transmitting blocks of data called datagrams that are output from the UDP function, from the base transceiver station BTS as source to the media gateway
25 as destination. A detailed description of the IP function is published in "DOD Standard Internet Protocol", RFC 760, IEN 128, 1980 (<http://www.ietf.cnri.-reston.va.us/rfc/rfc0760.txt>). The resulting data stream output has a data rate between 0 and 15 kbps.

30

The IP function in the second stack 32 of figure 2 outputs the datagrams to a Layer_2 L2, which function fulfils for example ATM (Asynchronous Transfer Mode). The SDH/SONET

(Synchronous Digital Hierarchy/ Synchronous Optical Network) is an example for a protocol of a Layer_1 L1, which processes and prepares the from L2 received data for sending to the media gateway 10 via the direct route or connection 11, according to figure 1.

In the following, the case of downlink data transmission within the second stack 32 of the base transceiver station BTS is described in more detail.

10

In the direction of the downlink transmission, the sequence of functions of the second protocol stack 32 in the base transceiver station BTS comprises the Layer_2 L2 function, the Layer_1 L1 function, the IP function, the UDP function, the DTX function, the Relay function, the RA0 function, the RA1 function, the RA1' function and the FEC function in this order wherein the data stream output from the FEC function of the second stack 32 is input to FEC function of the first stack 31 of the mobile station TE/MS.

20

First, the data stream or datagrams, which are fed from the L1 function of the third stack 33 in the media gateway Media Gateway via the direct connection 11 in the downlink direction to the L1 function in the second stack 32 of the base transceiver station BTS, are processed and prepared in the L1 and L2 function of the second stack for further processing in the subsequent IP function, which is terminated in the second stack 32 in downlink direction. The from IP layer resulting datagrams are output to the UDP function.

30

The UDP function provides a procedure for converting the datagrams received from the IP function into a synchronous

data stream to be output to the DTX function. In this example the UPD function is terminated in the second stack 32 of the base transceiver station.

- 5 The DTX function performs the same function as already explained with regard to the DTX function in uplink direction. But in downlink transmission the DTX function of the second stack 32 can be inactive since all superfluous information RLP frames in downlink direction have been
10 already discarded or filtered out in a further DTX function implemented in the third stack 33 of the media gateway, which is described later.

- The subsequent RA0 function converts the incoming
15 asynchronous user data stream, relayed from the DTX function, to the synchronous data stream. The synchronous data stream is fed to the RA1 function, which converts the incoming synchronous user data stream to the synchronous data stream having a data rate being higher than the
20 incoming data rate. For instance, the RA1 function converts the incoming synchronous data stream having the data rate of 9.6 kbps into a synchronous data stream having the intermediate data rate of 16 kbps. The synchronous data stream resulting from the RA1 function is fed to the RA1'
25 function of the second protocol stack 32.

- Subsequently, the RA1' function of the protocol stack 32 of the base transceiver station BTS converts the incoming synchronous data stream that is output from the RA1
30 function to a synchronous data stream having a data rate being lower than the incoming data rate. For instance, the RA1' function converts the incoming synchronous data stream having the intermediate data rate of 16 kbps into a

synchronous data stream having the radio frequency data rate of 12 kbps. The synchronous data stream resulting from the RA1' function is fed to the FEC function in the base transceiver station BTS.

5

The FEC function of the second stack 32 in downlink direction provides a forward error correction of the data stream received from the RA1' converter and adds corresponding redundant information for error correction to the RA1' data stream. Therefore, the FEC function increases the incoming RA1' data rate, for instance, from 16 kbps to 22.8 kbps. The data stream output from the FEC function is forwarded via the radio link to the first stack 31 of the mobile station TE/MS.

15

The third protocol stack 33 shown in figure 2 which is implemented in the media gateway Media Gateway comprises a sequence of protocol functions, an user data stream has to pass through.

20

The protocol function sequence in the direction of uplink transmission in the protocol stack 33 comprises the above described L1 function, L2 function, IP function, the UDP function, the DTX function, the RLP function, a L2R function and a X function in this order wherein the data stream output from the X protocol stack is sent to the further network 2. The term X protocol stack represents a general description for a fixed network protocol stack implemented in the media gateway, which structure differs in dependence on the art of the further network. The fixed network protocol stack could be, for instance, a modem stack, an ISDN digital data stack or an access server protocol stack providing a data stream with a data rate of

30

64 kbps. In figure 2 the X protocol stack receives the data stream prepared by the L2R function and provides an output data stream to the further network 2.

- 5 In the following also according to figure 1, the case of uplink data transmission within the third stack 33 of the media gateway Media Gateway is described in more detail.

First, the data stream or datagrams, which are fed from the
10 L1 function of the second stack 32 in the base transceiver station 8 via the direct connection 11 in the uplink direction to the L1 function in the third stack 33 of the media gateway, are processed and prepared in the L1 and L2 function of the third stack for further processing in the
15 subsequent IP function. The resulting datagrams of IP function are output to the UDP function.

The subsequent UDP function provides a procedure for converting the datagrams received from the IP function into
20 a synchronous data stream to be output to the DTX function, i.e. the UDP function is terminated in the third stack 33 of the media gateway.

The following DTX function performs the same function as
25 already explained with regard to the DTX function in uplink direction of the second stack 32 in the base transceiver station BTS. But in uplink transmission the DTX function of the third stack 33 can be set inactive since all superfluous information RLP frames in uplink direction have
30 been already discarded or filtered out in the DTX function implemented in the second stack 32 of the base transceiver station BTS.

The subsequent RLP function processes the incoming data stream that is in the above described format of RLP frames and prepares a data stream to be processed in the subsequent L2R layer. Within this example the RLP layer is terminated in the third stack 33 of the media gateway in uplink transmission of data.

The L2R function converts the incoming synchronous user data stream that is output from the terminated RLP function to a synchronous data stream that can be processed in the subsequent X protocol stack. The L2R layer is terminated in the third stack 33 of the media gateway in uplink transmission of data.

In the following, the case of downlink data transmission within the third stack 33 of the media gateway Media Gateway is described in more detail.

In the direction of downlink transmission, the sequence of the third protocol stack 33 in the media gateway comprises the X protocol stack, the L2R function, the RLP function, the DTX function, the UDP function, the IP function, the L2 function and the L1 function in this order wherein the data stream output from the L1 function of the third stack 33 is input to the L1 function of the second stack 32 of the base transceiver station BTS in the case of downlink transmission.

First, in the downlink direction, the X protocol stack representing the fixed network protocol stack receives the data stream from the further network 2 and prepares and converts the received data stream or user information stream to an synchronous data stream to be processed in the

subsequent L2R function. The fixed network protocol stack provides, for instance, a data stream of 9.6 kbps from the input ISDN data stream of 64 kbps.

- 5 The Layer_2 Relay L2R function, then, converts the incoming synchronous user data stream that is output from the X protocol stack to a data stream that can be processed by the RLP function or entity in the third protocol stack 33. A more detailed description of the L2R function is
10 disclosed in GSM 04.22. The data stream resulting from the L2R function is fed to the subsequent RLP function.

The RLP function processes the incoming data stream into RLP frames that are sent in strict alignment with the radio
15 transmission data. The function and the structure of the RLP frames is the same as already explained with regard to the RLP layer in the first stack 31 in the mobile station TE/MS.

- 20 The subsequent DTX function performs a frame suppression or discarding function for suppressing the transfer of an information frame generated in the RLP layer or entity in the third stack 33 of the media gateway within the second layer if the RLP information frame does not comprise any
25 user information. The procedure and structure of the DTX function in the third stack 33 is the same as already explained with regard to the DTX function implemented in the second stack 32 of the base transceiver station BTS. The data stream output from the DTX layer is input to the
30 following UDP function.

The UDP function provides the procedure for converting the synchronous data stream output from the DTX function into a

data stream prepared for the subsequent IP function within the third stack 33 of the media gateway. Again, the UDP header format comprises, inter alia, a source port field and a destination port field. The destination port field is loaded with address information assigned to the base transceiver station BTS and the source port field is loaded with address information assigned to the media gateway.

The data stream output from the UDP function is input to the IP function in the third stack 33 of the media gateway. The IP function, inter alia, is designed for use in interconnection of the base transceiver station BTS and the media gateway Media Gateway for packet switched communication and data transmission between them. Again, but in downlink direction within the third stack 33, the IP function provides for transmitting blocks of data called datagrams, that are output from the UDP function, from the media gateway Media Gateway as source to the base transceiver station BTS as destination. The IP function in the third stack 33 of figure 2 outputs the datagrams to the L2, which processes the datagrams and releases the prepared data to Layer_1 L1. The L1 is responsible for preparing the data stream to be sent to the base transceiver station BTS via the direct route or connection 11. The resulting data stream output in downlink direction has, for instance, the data rate of 9.6 kbps or 13 kbps.

Figure 3 shows a schematic block diagram of a second user plane protocol stack for synchronous non-transparent bearer services in the cellular telephone network of figure 1. Figure 3 shows a first protocol stack 41 being implemented in the mobile station TE/MS, a second protocol stack 42 being implemented in the base transceiver station BTS and a

third protocol stack 43 being implemented in the media gateway Media Gateway. The first to third protocol stacks 41, 42 and 43, that constitute together the second user plane protocol stack, are again established to provide the
5 transmission of user data.

Since the procedure of downlink and uplink direction in case of synchronous non-transparent bearer services is similar to the above described procedure of downlink and
10 uplink for asynchronous non-transparent bearer services, in the following it will not be treated in every detail. The significant difference between these two user planes lays in the removal of the RA0 layer in the first protocol stack 41 implemented in the mobile station. This is done because
15 of the fact that the application layer already delivers synchronous data therefore there is no need of data transformation done by RA0 function.

Figure 4 is a schematic block diagram of a third user plane
20 protocol stack for asynchronous transparent bearer services in the cellular telephone network of figure 1.

This user plane includes also three protocol stacks implemented in the corresponding network entities. A first
25 protocol stack 51 is being implemented in the mobile station TE/MS, a second protocol stack 52 is being implemented in the base transceiver station BTS and a third protocol stack 53 is being implemented in the media gateway Media Gateway. The whole procedure of the data transmission
30 in uplink or downlink direction is to be based on the user plane protocol stack for asynchronous non-transparent bearer services described regarding to figure 2. In the

following the significant differences to the described example of figure 2 will be presented.

As already explained a transparent bearer service does not
5 guarantee a reliable data transmission at the level of the
link layer. With other words no L2R and no RLP functions
are supported for this kind of data transmission. With
regard to the protocol stack 51 of figure 4 implemented in
the mobile station TE/MS the sequence of the protocol
10 functions does not comprise the L2R and RLP layer.

The transparent bearer service is applied for example for
applications transmitting real-time data such as audio or
video. The in the transparent bearer service unavailable
15 RLP function causes a faster transport of data due to the
fact that the occurred errors are not corrected via a
retransmission. This kind of data transmission is allowed
by applications, likes audio or video, which tolerate some
error rate. The missing RLP function leads yet to a problem
20 that no guarantee is given for the right order of the
received packets. The UDP as transport protocol allocated
directly above a network layer, for example Internet
Protocol IP, is a typical unreliable transport protocol for
real-time application, which also does not take care for
25 reordering of the not in the sent order received data
packets. Therefore in order to take care of reordering the
packets or of the time-critical issues a so-called real-
time protocol can be introduced above the UDP. The real-
time protocol can be implemented for example by the Real
30 Time Protocol RTP or any other mechanism providing similar
functionality. In the second protocol stack 52 and in the
third protocol stack 53 of figure 4 as an example for a
real-time protocol the RTP layer is being implemented.

Detailed information on the RTP function are described in "RTP: A Transport Protocol for Real-Time Applications" published by H. Schulzrinne, et al in 1996 (<http://www.ietf.cnri.reston.va.us/rfc/-rfc0760.txt>).

5

Since there is no RLP layer and therefore no RLP frames a discontinuous transmission function DTX shown in figure 4 is different in comparison with a DTX function shown in figure 2 or figure 3. The DTX function of the second stack
10 52 can be implemented as follows. The RA0 layer which is implemented in the interworking function in the GSM network should be moved to the base transceiver station BTS. In that case, the media gateway would relay any asynchronous data stream received from the fixed network side to the
15 base transceiver station BTS. The base transceiver station BTS would terminate the RA0 function to yield a synchronous stream to be sent to the mobile station TE/MS. This enables the media gateway to omit any empty frames. If the base transceiver station BTS has not received any data from the
20 interworking function to forward to the mobile station TE/MS, the base transceiver station BTS generates empty frames. The described case occurs in uplink direction. In downlink direction the DTX function of the second protocol stack 52 can be inactive since all empty or superfluous
25 information frames have been already discarded or filtered out in a further DTX function implemented in the third protocol stack 53 of the media gateway.

Also a DTX function implemented in the third protocol stack
30 53 of the media gateway in figure 4 performs a frame suppression or discarding function for suppressing the transfer of an information frame which does not comprise any user information or is empty. The procedure and

structure of the DTX function in the third stack 53 can be the same as already explained with regard to the DTX function implemented in the second stack 52 of the base transceiver station BTS. But in uplink transmission the DTX function of the third stack 53 can be set inactive since all empty information frames in uplink direction have been already discarded or filtered out in the DTX function implemented in the second stack 52 of the base transceiver station BTS.

10

Fig. 5 is a schematic block diagram of a fourth user plane protocol stack for synchronous transparent bearer services in the cellular telephone network of figure 1.

15 Fig. 5 shows a first protocol stack 61 being implemented in the mobile station TE/MS, a second protocol stack 62 being implemented in the base transceiver station BTS and a third protocol stack 63 being implemented in the media gateway Media Gateway. Between these three protocol stacks a transmission of user data is performed. Within the considered user plane a transmission of synchronous bearer services is carried out. This means an application already delivers a synchronous data flow, therefore a RA0 function is not required any more. Further the data transmission is transparent, this means a RLP function is not available. Since within the user plane protocol stack for synchronous transparent bearer services as well no RLP frames are existing as a RA0 function is not available, the frame suppression procedure or discarding function for suppressing the transfer of an information frame which does not comprise any user information or is empty can not be performed. This kind of bearer services can be used for transport of a facsimile service, as it is done in this

20
25
30

example with regard to figure 5. Within the third protocol
63 a supplementary layer, a so-called facsimile adaptation
layer is implemented. This layer performs converting of the
facsimile data between the circuit switched network and a
5 further network.

The whole procedure for data transmission in uplink and
downlink direction is to be performed in a similar way as
it is described and explained in the example of
10 asynchronous non-transparent bearer services.

Figure 6 is a schematic block diagram of a fifth user plane
protocol stack for asynchronous non-transparent high-speed
circuit-switched data bearer services in the cellular
15 telephone network of figure 1.

Figure 6 shows a first protocol stack 71 being implemented
in the mobile station TE/MS, a second protocol stack 72
being implemented in the base transceiver station BTS and a
20 third protocol stack 73 being implemented in the media
gateway Media Gateway. The first to third stacks 71, 72 and
73 are established to provide the transmission of user
data.

25 The considered user plane provides a solution for High
Speed Circuit Switched Data service (HSCSD) as an example
of so-called enhanced GSM data service. With HSCSD it is
possible to transfer data with higher bandwidth, exactly
with the performance of 4×9.6 kbit/sec or 4×14.4 kbit/sec.
30 A detailed description of HSCSD can be find in GSM 02.34
and GSM 03.34.

As a basis for explaining the transport of HSCSD an example of asynchronous non-transparent bearer services has been chosen. Every other user plane can be adapted to the HSCSD in a similar way.

5

In comparison with figure 1 an additional layer for a communication over a radio link in the mobile station MS and in the corresponding protocol stack in the base transceiver station BTS is introduced, a so-called S/C (Split/Combine) layer. The task of the S/C function is to split the output of the higher layer into multiple channels each 9.6kbit/sec or 14.4 kbit/sec and to combine the output of the lower layer into one data flow of a higher layer. In the first protocol stack 71 of figure 6 a S/C layer splits the data coming from RLP layer with the bitrate between 9.6 kbit/sec and 57.6 kbit/sec into 4 channels and in the uplink direction the S/C combines the data coming from RA1' into one RLP data flow. A similar converting procedure is done in the second protocol stack 72 of figure 6 between a RA1' and RA1 layer.

The complete data transmission in uplink and downlink direction between a mobile station and a further network is comparable with the data transmission described in figure 1.

Claims

1. Communication network part (1) comprising:
interface means (20) for coupling the cellular telephone
5 network (1) to a further network (2), the interface means
(20) comprising signalling information exchange function
between the cellular telephone network (1) and the further
network (2) and user or payload information exchange
10 function between the cellular telephone network (1) and the
further network (2) and
a first layer (3) for transferring signalling information
assigned to a telephone call being processed in the
cellular telephone network and
a second layer (4) for transferring payload information
15 assigned to the telephone call being coupled to the
interface means (20), wherein
the second layer comprising:
information frame generating means for generating an
information frame comprising user information of the
20 telephone call and being transferred to and from the
interface means (20) on a direct route (11) assigned to the
telephone call within the second layer (4), and
comprising a frame suppressing function for suppressing the
transfer of an information frame within the second layer
25 (4) if the information frame does not comprise any user
information, and
radio network means comprising a rate adaptation function
for a rate adaptation of the payload information transfer
assigned to the telephone call.

30

2. Communication network part (1) of claim 1, wherein the
second layer (4) of the cellular telephone network (1)
comprises a number of base transceiver stations (7, 8, 9),

wherein the base transceiver station (8) being directly connected to the interface means (20) for user information exchange within the second layer (4), and wherein the base transceiver station (8) comprises the frame generating
5 means having the frame suppressing function.

3. Communication network part (1) of claim 2, wherein the interface means (20) comprises media gateway means (10) for user information exchange between the cellular telephone
10 network (1) and the further network (2) and to be coupled directly to the base transceiver stations (8), and wherein the media gateway means (10) comprises the frame generating means having the frame suppressing function.

15 4. Communication network part (1) of one of the preceding claims, wherein an information frame comprises specifying information specifying that the information frame does not provide any user information and wherein the information frame suppressing function discards an information frame
20 received if it comprises the specifying information.

5. Communication network part (1) of one of the preceding claims, wherein an information frame comprises a receive sequence number that designates the next information frame
25 to be sent, and wherein the information frame suppressing function discards a current information frame if the receive sequence number of the current information frame is equal to the receive sequence number of the previous information frame received.

30

6. Communication network part (1) of one of the preceding claims, wherein a radio link protocol (RLP) for generating

radio link protocol frames for data transmission is implemented in the frame generating means.

- 5 7. Communication network part (1) of one of the preceding claims, wherein the second layer (4) comprising a first protocol stack being implemented in a mobile station (5), a second protocol stack being implemented in a base transceiver station (8) and a third protocol stack being implemented in 10 a media gateway (10) of the interface (20), wherein the first to third protocol stacks are established to provide a transmission of user data within the second layer (4) in an uplink and downlink direction of data transmission.
- 15 8. Communication network part (1) of one of the preceding claims, wherein the transmission of user data provided by a communication network is an asynchronous non-transparent bearer services.
- 20 9. Communication network part (1) of one of the preceding claims, wherein the transmission of user data provided by a communication network is a synchronous non-transparent bearer services.
- 25 10. Communication network part (1) of one of the preceding claims, wherein the transmission of user data provided by a communication network is an asynchronous transparent bearer services.
- 30 11. Communication network part (1) of one of the preceding claims, wherein the transmission of user data provided by a communication network is an asynchronous non-transparent bearer services.

12. Communication network part (1) of one of the preceding claims, wherein the transmission of user data provides the HSCSD (High Speed Circuit Switched Data) bearer services,
5 for which the first protocol stack being implemented in a mobile station (5) and the second protocol stack being implemented in a base transceiver station (8) contain a S/C (Split/Combine) function.
- 10 13. Communication network part (1) of one of the preceding claims, wherein in the synchronous bearer service bits of a data stream are transmitted regularly and continuously on the basis of a time clock and in the asynchronous bearer service the transmission of bits is not aligned on a
15 regular time clock.
14. Communication network part (1) of one of the preceding claims, wherein the non-transparent bearer service provides a reliable data transmission and wherein the transparent
20 bearer service does not guarantee a reliable data transmission
15. Communication network part (1) of one of the claims 7 to 12 or 14, wherein in the reliable data transmission a
25 RLP (Radio Link Protocol) is available.
16. Communication network part (1) of one of the preceding claims, wherein the radio network mean is the base transceiver stations (8).
30
17. Communication network part (1) of one of the preceding claims, wherein the radio adaptation of the payload information transfer assigned to the telephone call towards

a mobile station (5) is performed in the base transceiver stations (8).

18. Communication network part (1) of one of the preceding
5 claims, wherein the radio adaptation of the payload
information transfer assigned to the telephone call towards
the media gateway is performed in the base transceiver
stations (8).

10 19. Method for operating in a communication network part
(1) comprising:
interface means (20) for coupling the cellular telephone
network (1) to a further network (2), the interface means
(20) comprising signalling information exchange function
15 between the cellular telephone network (1) and the further
network (2) and user or payload information exchange
function between the cellular telephone network (1) and the
further network (2) and
a first layer (3) for transferring signalling information
20 assigned to a telephone call being processed in the
cellular telephone network and
a second layer (4) for transferring payload information
assigned to the telephone call being coupled to the
interface means (20), wherein
25 the method comprising within the second layer (4):
generating an information frame comprising user information
of the telephone call and being transferred to and from the
interface means (20) on a direct route (11) assigned to the
telephone call within the second layer (4), and
30 suppressing the transfer of an information frame within the
second layer (4) if the information frame does not comprise
any user information, and

adapting the transfer rate of the payload information assigned to the telephone call within radio network means.

20. Method of claim 19, wherein an information frame
5 comprises specifying information specifying that the information frame does not provide any user information is provided and wherein the information frame suppressing function discards an information frame received if it comprises the specifying information.
- 10 21. Method of one of the claims 19 or 20, wherein an information frame comprises a receive sequence number that designates the next information frame to be sent, and wherein the information frame suppressing function discards
15 a current information frame if the receive sequence number of the current information frame is equal to the receive sequence number of the previous information frame received.
- 20 22. Method of one of the claims 19 to 21, wherein the adapting the transfer rate of the payload information assigned to the telephone call towards a mobile station (5) is performed within a radio network mean.
- 25 23. Method of one of the claims 19 to 21, wherein the adapting the transfer rate of the payload information assigned to the telephone call towards a base transceiver station (8) is performed within a radio network mean.
- 30

Abstract

The present invention relates to a communication network part, and a method for operating in a communication network. The communication network part comprises a first layer for transferring signalling information assigned to a telephone call being processed in the cellular telephone network and a second layer for transferring payload information assigned to the telephone call. Further an interface mean couples the cellular telephone network to a further network. The interface means comprise a signalling information exchange function and user or so-called payload information exchange function between the cellular telephone network and the further network. The first layer and the second layer of the cellular telephone network being coupled to the interface means. The second layer comprises information frame generating means for generating an information frame comprising user information of the telephone call and being transferred to and from the interface means on a direct route assigned to the telephone call within the second layer and a frame suppressing function for suppressing the transfer of an information frame within the second layer if the information frame does not comprise any user information. The second layer comprises also radio network means comprising a rate adaptation function for a rate adaptation of the payload information transfer assigned to the telephone call. With this step the rate adaptation function is shifted from an interworking function into a radio network means, for example base transceiver station (BTS).
